

◆ **Outline**

- **Where are we and where are we going?**
- **Introduction to VLHC — the options and the issues**
- **High-field magnet R&D**
- **Some answers to the big questions**

◆ Where are we now?

- The Tevatron is the world's highest energy machine, and has great frontier physics for the next 6–8 years.
- The LHC is being built at CERN. The U.S. is participating in the machine and the detectors.
- The world HEP community is searching for the right thing to do as the next step after the LHC.

The choices as we see them now:

- ☞ **NLC** — $E_{\text{collision}} \sim 1 \text{ TeV}$ Question: Will 1 TeV be interesting?
- ☞ **Muon Collider** — $E_{\text{collision}} \sim 4 \text{ TeV}$ Question: Will it work?
- ☞ **VLHC** — $E_{\text{collision}} \sim 5 - 10 \text{ TeV}$ Question: Can we afford it?

◆ The Real Question

● Is LHC the end of the road for accelerator-based HEP?

- ❖ *When will we know where we want to go? (Via physics, not politics)*
- ❖ *Can we risk starting the trip without the destination clearly in mind?*
- ❖ *How do we pay for the ticket?*

◆ The Very Large Hadron Collider

● *The Snowmass-96 VLHC*

A 50 TeV x 50 TeV proton-proton collider

Luminosity $\geq 10^{34} \text{ cm}^{-2}\text{s}^{-1}$

Injection energy = 3 TeV ??

Three colliders were studied, each with different magnetic field strengths:

1.8 T	9.5 T	12.5 T
-------	-------	--------

The goal was (and still is) to develop a workable collider that is affordable.

◆ Choosing the magnet strength

What are the magnet possibilities?

- ◆ Low field $B \leq 2 \text{ T}$ Fermilab R&D
- ◆ Moderate field $4 \text{ T} < B < 9 \text{ T}$ Tevatron, UNK, HERA, RHIC, LHC
- ◆ High field $9 \text{ T} < B \leq 12 \text{ T}$ Fermilab R&D with LBL & KEK
- ◆ Very high field $B > 12 \text{ T}$ BNL & LBNL R&D
- Field strength choice is complicated by many issues:
 - Ring circumference
 - Synchrotron radiation
 - Accelerator physics issues
 - Magnet costs; Total cost
 - Superconducting materials choices
 - Many more...

◆ Choosing the magnet strength

 For example — Ring size:

2 T Magnets → 500 km

10 T Magnets → 130 km

12.5 T Magnets → 104 km

500 km Pipetron Map Study

500 km Pipetron Map Study

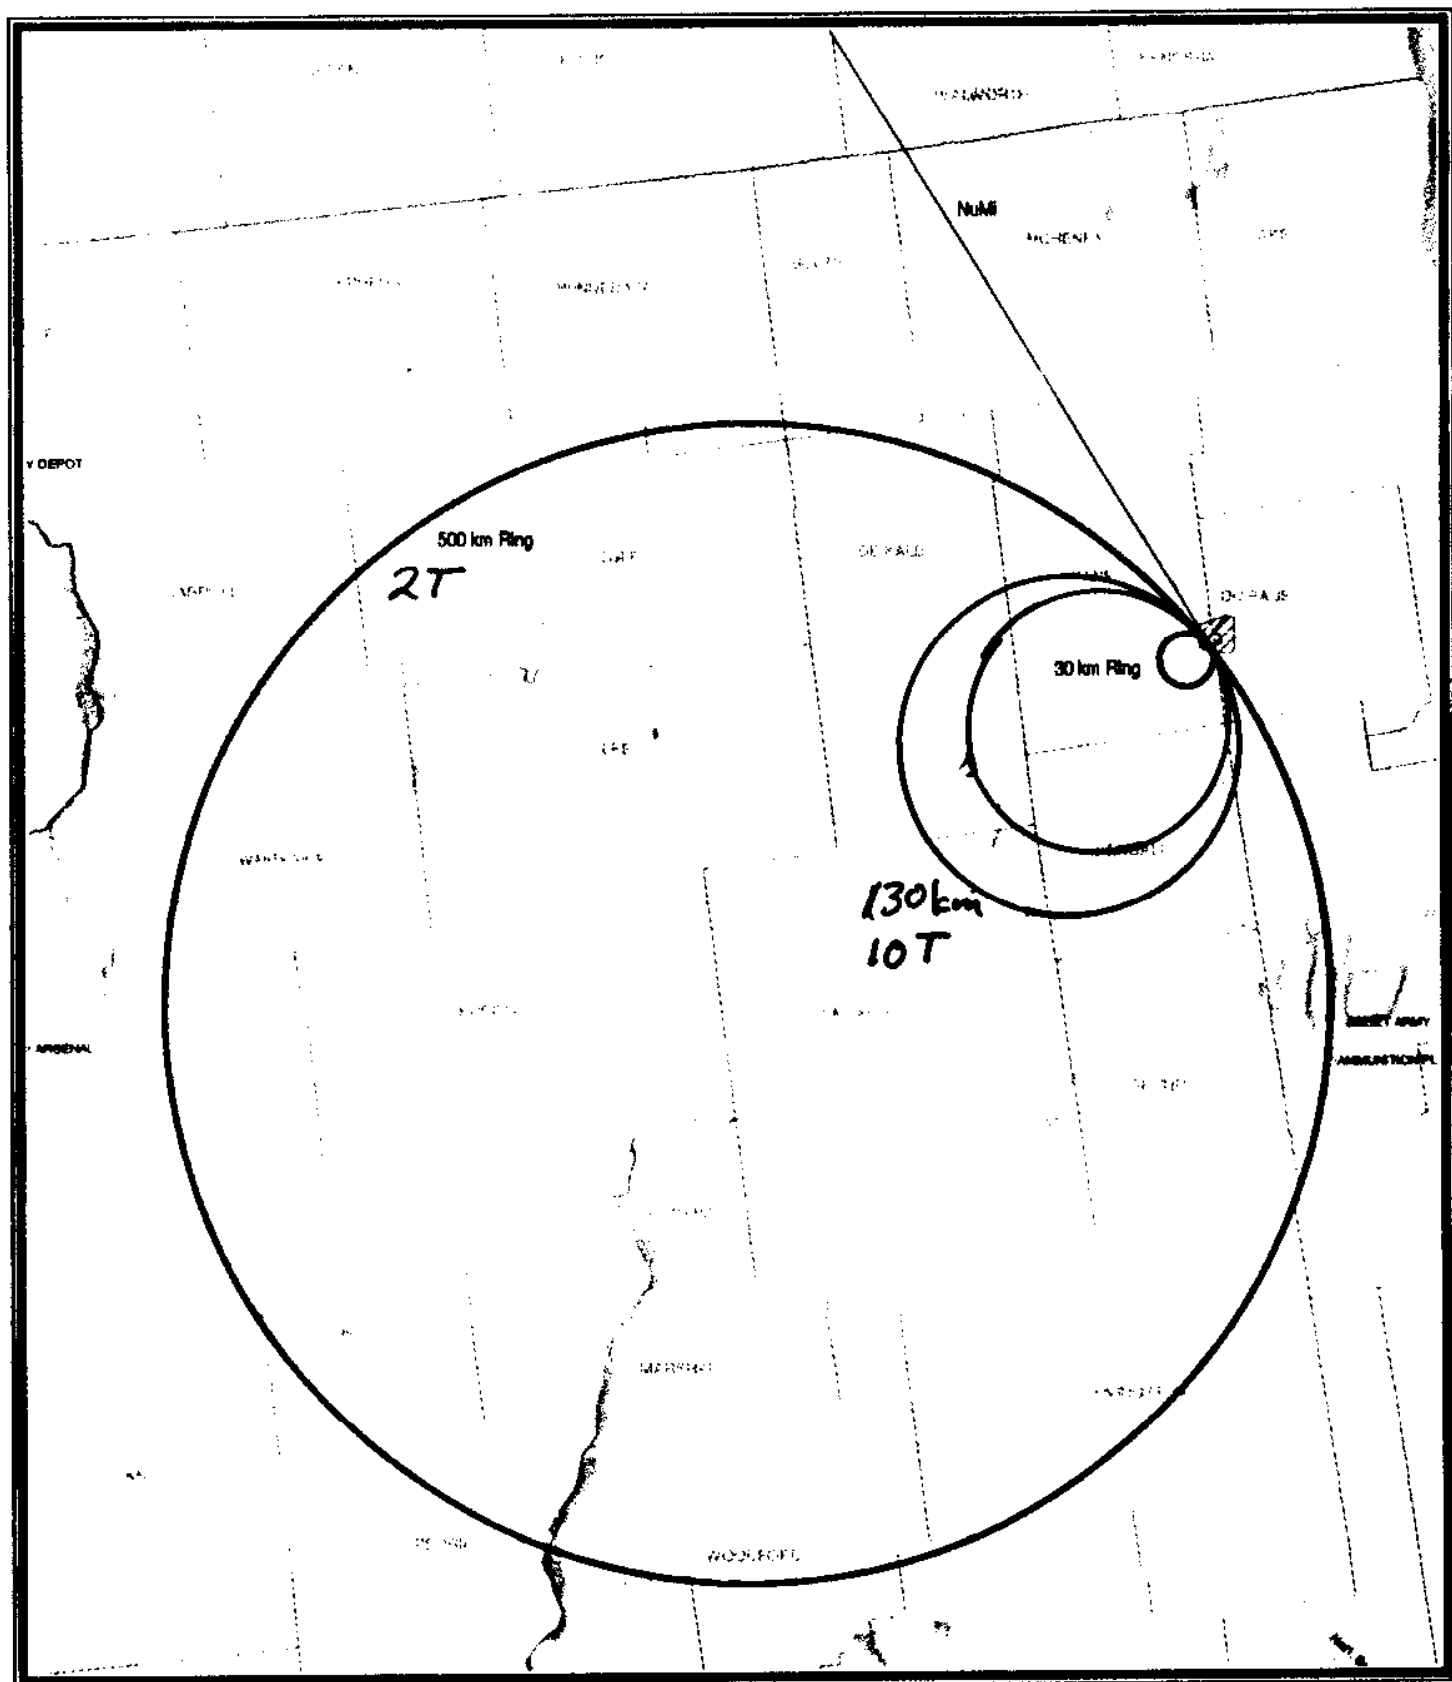

Table I : Machine parameters

Parameter	High field-new technology	High field-known technology	Low Field	Units
CM Energy	100	100	100	TeV
Dipole field	12.6	9.5	1.8	T
Circumference	104	138	646	km
Synchrotron radiation damping time (horizontal amplitude)	2.6	4.6	<i>antidamped</i>	hr
Initial/peak luminosity	.35/1.2	.35/1.0	1/1.	$10^{34} \text{ cm}^{-2} \text{ sec}^{-1}$
Integrated luminosity per day	500	500	700	pb^{-1}

Number of bunches	20794	27522	129240	
Equilibrium emittance (x)	144.2	62	1.8	$10^{-3} \pi \mu\text{m-rad}$
Bunch spacing	16.7	16.7	16.7	nsec
Beam stored energy	.89	1.18	9.73	GJ
Synchrotron radiation power/ring	189	143	48	kW
Total protons/ring	1.1	1.5	12.2	10^{14}
Initial/peak interactions/crossing	7.5/21.5	7.5/21.5	21.5/21.5	
Beam lifetime (pp collisions only)	34	45	130	hr
$\sigma_{\text{inelastic}}$	130	130	130	mbarn
Initial beam-beam Δv (total)	5.1	5.1	11.6	10^{-3}
Revolution frequency	2.89	2.18	.46	kHz
Synchrotron frequency	8.9	5.8	.86	Hz
Rf Voltage	100	100	100	MV
Radio-frequency	360	360	360	MHz
Energy loss/turn	3678	2778	526	keV
Rms relative energy spread(collison)	15.6	18.0	39.0	10^{-6}
Fill time	16.3	16.3	28	min.
Acceleration time	5.8	7.6	35.9	min.
Total time: fill and accelerate	22.1	24	63.9	min.
Longitudinal impedance threshold: $\frac{Z_{ }}{n}$ (collision)	3.6	2.7	1.1	Ω
Transverse impedance threshold: Z_{\perp} (injection)	731	635	250	$\text{M}\Omega/\text{m}$
Resistive-wall transverse impedance: $Z_{RW}(\frac{c}{\sigma_s})$ (injection)	0.4	0.5	98	$\text{M}\Omega/\text{m}$
Resistive-wall multibunch instability growth time	472	310	.36	turns
Total current	.05	.05	.09	Amp
Peak current(inj)	3.6	3.6	4.2	Amp
$\langle \beta \rangle$	255	255	382	m
Tune	65	86	269	
Half cell length (assumed 90°cells)	200	200	300	m
Beam pipe radius	1.65	1.65	1.0	cm
Beam pipe	Cold, Cu	Cold, Cu	Warm, Al	

◆ *Dear, we need to talk about synchrotron radiation.*

- Synchrotron radiation is:

Bad: it puts power into the cryogenics & ruins the vacuum.

Cryogenic load: @ 50 TeV, 10 T

$$W/\text{turn} = 8 \times 10^3 E^4/\rho = 2 \times 10^3 E^3 B = 2.75 \text{ MeV/turn}$$

$$P_{\text{total}} = IW = 0.1 \text{ A} \times 2.75 \text{ MeV} = 275 \text{ kw/beam} = 550 \text{ kw total}$$

For a shield at 80 K, this is about 6 MW at the plug. Not too bad!

Vacuum load:

$$P/\text{meter} = P_{\text{total}}/2\pi\rho = 1 \times 10^{-4} E^2 B^2 = 2.6 \text{ W/m} \quad \text{Almost 10 times the LHC!}$$

- Synchrotron radiation is:

Good: it makes the beam emittance (size) smaller.

$$\tau_{\text{damping}} \propto 1/EB^2 \cong 4 \text{ hrs (horiz)} \quad \begin{array}{l} \text{Beam size gets smaller} \\ \text{Luminosity increases!} \end{array}$$

LHC vacuum with synchrotron radiation.

Synchrotron radiation photons desorb strongly bound gas molecules which are cryosorbed and gradually accumulate on the cold beam screen.

Scattered/reflected photons re-desorb these molecules at a rate increasing with coverage, leading in turn to an increasing gas density (pressure).

The increase in pressure due to 'recycling' of molecules increases the probability for gas to escape through the pumping slots and to be permanently cryosorbed on the 1.9K cold bore. This effect stabilises the gas density in the beam pipe to a safe value.

Without pumping holes, the beam screen would have to be warmed-up periodically to pump-out any condensed gas.

Test run at INP in Novosibirsk, scaled to LHC parameters and for initial operation at $\sim 1/10$ of the nominal beam current illustrating the effect of warming-up the beam screen.

Fig. 3: Beam parameters during a store for high-field RLHC.

Fig. 4: Integrated luminosity of 10 hour store vs. initial rms emittance for RLHC options. The integrated luminosity of the two high-field cases is almost independent of the initial emittance because of synchrotron radiation damping.

◆ *Magnet Options for VLHC*

- *Low-field magnets ($B \leq 2 \text{ T}$)*
 - Uses superferic magnets
magnet is elegant and simple
the low-field magnet may be cheaper
(but it's the total cost that counts)
 - There are some machine issues related to the large circumference
 - No synchrotron radiation damping

Transmission Line Magnet

KEY FEATURES:

- Simple Cryogenic System
- Small Superconductor Usage
- Small Cold Mass
- Low Heat Leak
- Continuous in Long Lengths
- No Quads or Spool Pieces
- Warm Bore Vacuum System
- Standard Construction Methods

◆ *Magnet Options for VLHC*

- *Moderate-field magnets ($4\text{ T} < B < 9\text{ T}$)*

Uses $\cos(\theta)$ NbTi magnets.

- Magnet and machine are well understood
- Fermilab is doing this R&D via LHC quadrupole program

Little synch. radiation damping except at high end

- High-field NbTi magnets are hard to make
- Needs expensive 1.8 K cryogenics for $B > 7\text{ T}$

- Not actively being pursued for VLHC

1HC DIPOLE : STANDARD CROSS-SECTION

◆ Magnet Options for VLHC

- *Very-high-field magnets ($B > 12\text{ T}$)*
 - oodles of synchrotron radiation damping
 - too much synchrotron radiation power!
 - limited design options for magnets

Neither $\cos(\theta)$ nor NbTi are possible
Forces are huge

- Conclusion: Very high field is not worth the effort

Only a small decrease in circumference
Additional emittance damping is not needed
Too much synchrotron radiation
Magnets will be much more costly

HTS ? Who knows?

Some interesting progress lately – 1 kA cable
A moderate effort keeps us connected

US LHC ACCELERATOR PROJECT *brookhaven - fermilab - berkeley*

III. Model Magnet Program

◆ Magnet Options for VLHC

- *High-field magnets ($\sim 9\text{ T} < B \leq 12\text{ T}$)*

- lots of synchrotron radiation damping
- accelerator physics issues are understood (?)
- numerous design options for magnets

Cos(θ) NbTi at 1.8 K for $B < 10\text{ T}$

Material is well understood, available and sort of cheap.
Requires very high mechanical and material tolerances

Cos(θ) Nb₃Sn (Al?) at 4.5 K for $B \leq 12\text{ T}$

Material needs R&D to improve performance and reduce cost
Mechanical and material tolerances are relaxed relative to NbTi
Cos(θ), horizontal 2-in-1 uses the least superconductor and steel

Block designs Nb₃Sn (Al?) for $B > 10\text{ T}$

There is a very promising concept — common coil 2-in-1
May have simple assembly options, small aperture

◆ VLHC R&D GOALS

- *To design the machine and answer the accelerator physics questions*
- *To develop the magnets*
- *To reduce the cost, particularly of the magnets and tunnels*
- *To help find the answers needed to make an informed decision about the next collider*

◆ VLHC R&D PLAN

- *The major technical issue is the performance and cost of the magnets. What's the Fermilab high-field plan?*
- Concentrate on magnets...
 - One effort on a "traditional" Nb₃Sn magnet
Cos(θ), 10 T – 11 T, initially single aperture,
eventually horizontal 2-in-1
 - Another effort on a "speculative" Nb₃Sn magnet that
holds the promise of major cost reduction.
Two-in-one common planar coils, small aperture,
10 T – 11 T.
- And materials
 - A national R&D program to improve the performance
(J_c , deff, reaction time and temperature, strain
resistance...) of A-15 conductors
 - Coupled with a national R&D program to increase the
scale and reduce the cost of A-15 production.

Conclusions

- 30 mm bore dipole with 12-13 T design field using Nb₃Sn conductor at 4.2 K allows substantial savings in superconductor wrt 50 mm bore magnet with same design parameters.
- For these design parameters, shell and block design are substantially equivalent in terms of conductor efficiency and field quality.
- Vertical arrangement of the two apertures requires 50% larger yoke radius wrt horizontal arrangement in order to achieve same transfer function.

◆ VLHC R&D PLAN

● *What does such a plan cost?*

U.S. HEP Superconducting Magnet and Materials R&D (K\$)

Fiscal Year	<u>1998</u>	<u>1999</u>	<u>2000</u>	<u>2001</u>
High-field magnet R&D at LBNL	\$2150	\$2200	\$2300	\$3000
High-field magnet R&D at BNL	500	750	900	1500
High-field magnet R&D at Fermilab	700	1500	2700	3500
Superferric R&D at Fermilab	425	1100	1500	2000
Texas A&M University	345	350	500	700
Materials R&D in industry and universities*	200	400	600	2000
Total (not including G&A)	\$4320	\$6300	\$8500	\$12700

* This line is the sum of SC materials R&D in industry and universities funded by FNAL and LBNL in roughly equal amounts through FY2000. In FY2001 this is assumed to be separately funded.

◆ VLHC R&D PLAN (continued)

- *The materials R&D needs to increase after FY2002 to scale up production to study cost reduction possibilities.*
- *Other issues, like accelerator design and experimentation, and tunneling R&D need to be added.*
- *Don't forget overhead!*

The R&D cost grows to about \$20 million per year until one either starts building another accelerator, or decides to build a VLHC.

◆ New and improved materials

- ITER († now dead †) inspired much progress in Nb₃Sn and Nb₃Al, doubling J_c at high field, reducing AC losses, lowering cost.
- Large factors in J_c and cost are still possible, but the market promise has disappeared.
- We are trying to start a national R&D effort in Nb₃Sn and Nb₃Al R&D through the DOE and national labs. We asked for \$2M per year, starting in FY2000, increasing to ~\$4M per year in FY2003.
- Better J_c performance means smaller apertures and less superconductor
- Smaller filament diameter means better injection field
- Shorter and lower-temperature heat treatments mean cheaper fabrication
- **Scaling to large production runs means big cost reductions**

25 Applied Field, T

Conductor Cost Model

Dipole Magnet Touch Labor

◆ What about accelerator design?

- ★ Influence of magnetization on injection field
 - The magnetization effects for Nb₃Sn might be worse than for NbTi, due to higher J_c and effective filament diameter (d_{eff}) at injection.
 - The real problem is not the sextupole and decapole fields, which can be corrected, but their time dependence and the "snap-back."

Fermilab High Field Magnet R&D

Coil Magnetization Effect

$$18 \text{ kA} = 11 \text{ T} = 50 \text{ TeV}$$

◆ Choosing the injector energy

- ★ The HEB injector was chosen at 3 TeV at Snowmass_96
 - Based on highest-energy HEB that we thought could be filled by the 150 GeV Main Injector
- ★ Higher energy would be better
 - Could have ~ 4 TeV on site with 7 T SSC-type magnets at 4 K
 - Why stay on the site? Could go slightly larger for higher energy
 - But, an $E > 3$ TeV injector would be hard to fill from 150 GeV Main Injector.
- Could build a simple, conventional “Energy Doubler” in the Main Ring tunnel after the Tevatron shuts off. Much of the infrastructure still exists for a 150 GeV to 300 GeV accelerator. This would inject into 5 TeV HEB.
- If this 5 TeV booster were low-field (superferric), its circumference would be about 50 km, and could fill the Collider Ring in two or three cycles, reducing the injection dwell time.

◆ A VLHC Organization in the U.S.

● There is a U.S. national VLHC organization.

- Representatives of BNL, Fermilab, LBNL met at Fermilab in February, 1998 to discuss the form of a VLHC R&D organization in response to the Gilman Subpanel recommendation:

“The Subpanel recommends an expanded program of R&D on cost reduction strategies, enabling technologies, and accelerator physics issues for a VLHC. These efforts should be coordinated across laboratory and university groups with the aim of identifying design concepts for an economically and technically viable facility.”

- John Peoples asked the Directors of the BNL, LBNL and Cornell to appoint members of a VLHC Steering Committee.

BNL members:

Mike Harrison, Stephen Peggs

Cornell Member:

Gerry Dugan

Fermilab Members:

Peter Limon, Ernie Malamud (Secretary)

LBNL Members:

Bill Barletta, Jim Siegrist

◆ The VLHC Steering Committee

- The Steering Committee met in April, 1998, endorsed the concept of steering and promptly created three Working Groups with convenors to do the rowing.

Magnet Technology

Peter Wanderer (BNL), Bill Foster (FNAL), Ron Scanlan (LBNL)

Accelerator Technology

Chris Leehman (TJNAF), Waldo McKay (BNL), John Mariner (FNAL)

Accelerator Physics

Alan Jackson (LBNL), Shekhar Mishra (FNAL), Mike Syphers (LBNL)

- Some ground-rules
 - Initially, the US site of the VLHC is assumed to be Fermilab.
 - Focus on the technology and cost reduction for VLHC accelerators.

◆ The VLHC Steering Committee

● General charge to the working groups

Guided by the Snowmass-1996 parameter sets explore and develop innovative concepts that will result in significant cost reductions. Coordinate parameter sets and infrastructure requirements for the various options and designs with the other working groups.

- The working groups are open to all. Participation is welcomed from all US and foreign institutions.
- Organize workshops on the relevant issues in accelerator physics, magnet technologies, and accelerator technologies.
- Publish the results and hold an annual meeting to inform the community and set agendas for the coming year.

◆ **A National VLHC Organization**

- **Workshop on VLHC magnets**
 - Port Jefferson, LI, NY; November 16 – 18, 1998
Lead organizer: Peter Wanderer
- **Workshop on accelerator technology**
 - Thomas Jefferson Laboratory; February 8 – 11, 1999
Lead organizer: John Marriner
- **Workshop on accelerator physics**
 - Lake Geneva, WI; February 22 - 25, 1999
Lead organizer: Mike Syphers

● **Annual meeting**

Monterey, CA; June 28 - 30, 1999

Organizers: Bill Barletta, Jim Siegrist

◆ *Does accelerator-based HEP have a future?*

- *Yes, but only through*

Global Collaboration

- *We need to get serious: form a lab that is truly world-wide in scope.*
CERN is an example, but not a model.
- **One-third of the world economy has not contributed proportionally to HEP.**
They must be brought in as full partners.

◆ *Forming the world-wide collaboration*

- This is much harder than building an accelerator, but it must be done.
- We must put the politics, collaborations, cost sharing and public relations into place that will make the VLHC possible.

◆ Scaling the SSC to VLHC Energy

	SSC Base <u>1991 M\$</u>	Applicable to Fermilab <u>1991 M\$</u>	Scaled <u>1991 M\$</u>
